COUPLING THE FLEXIBILITY OF OVN WITH THE EFFICIENCY OF IOVISOR: ARCHITECTURE AND DEMO

#### Datacenter Networking

- Datacenter networking nowadays requires a mix of different technologies
  - Linuxbridge, OvS, OpenFlow, Linux containers/Docker with native services (e.g., DHCP), ...
- Difficult to write and deploy new functions

### The idea

- OVN
  - Addresses the problem of datacenter-wise orchestration
  - Runs with different cloud management systems
    (OpenStack, Mesos, ...)

 Bottom-layer technologies are the usual suspects

- IOVisor
  - Enables the creation of powerful network functions
    - Fast: running in kernel
    - Dynamically injectable at run-time
    - More flexible than OpenFlow actions

# IOVisor

- Community-driven open source project
- Provides **development tools** that enable the creation of modules (IOModules), which can be dynamically injected in the kernel at run-time
- IOModules can be used to build networking (e.g., network functions), security, and tracing applications

Community Tool	s, Applications a	nd IO_Modules

CPUs	Specialized HW	IO processors

## IOModule

Network Functions via Virtual/Physical Appliances

- **eBPF** is a virtual machine that extends the classical BPF instruction set architecture
  - Includes just-in-time (JIT) compiler and a powerful verifier that avoids inconsistencies, safety issues and hazards
  - Now part of the Linux kernel
- An IOModule is an eBPF program that performs a specific task
  - Bridge, Router, NAT, etc.
- IOModules can be combined to create complex services (*service chain*)

#### Hover

- Userspace daemon that interacts with the Linux kernel and handles the lifecycle of IOModules
- It exposes a **REST API** front-end for dynamically loading, configuring, linking different IOModules to create a *service chain*

## OpenStack - OVN architecture

- Northbound DB: high-level description of network services (logical switches, logical routers, etc.)
- northd: converts high-level descriptions from northDB to flow-like descriptions in southDB
- **Southbound DB**: logical flows and bindings tables, split per each compute node
- ovn-controller: executed on each hypervisor
  - Pushes the flows in OvS
  - Propagates any "physical" layer event (e.g., port down) to the upper layers
- **Open vSwitch**: in charge of the dataplane
- Bidirectional communication across the entire stack

#### IOVisor-OVN: architecture

- Starting point: keep OVN control plane, remove OvS dataplane
- IOVisor-OVN
  - Reads info from existing databases (NorthDB, SouthDB, ovs-localDB(s))
  - Maps changes (e.g., service requests) into IOModules
  - Exploits Hover to inject, configure and bind IOModules to network interfaces

## IOVisor-OVN: internals

- OVN Monitor: in charge of the synchronization with OVN databases
- Main Logic: processing logic that reacts to DB changes and/or notification coming from hypervisors
- Hover Ctrl: talks with Hover daemon running on each hypervisor

## OVN modifications

- Very limited
  - OVN-controller does not have to propagate commands to OvS (e.g., flow rules)
  - OVN does not have to start the OvS dataplane
- Some information are ignored
  - E.g., flow rules (that are no longer used to create bridged networks)

### IOVisor-OVN: current status (1)

- Proof of concept supports OpenStack creating a L2 network on a single compute node through the ML2 OVN mechanism driver
  - Reacts to the following changes in the OVN databases: a switch, a port or a port security rule is added, modified or removed
  - When appropriate, it injects and configures the L2Switch IOModule through Hover (e.g., attaching the VM vNIC to the IOModule)
  - Handles the dynamic mapping of logical names (e.g., "port12" coming from Neutron) with actual names (e.g., "tap34" coming from the hypervisor)

### IOVisor-OVN: current status (2)

- Created a minimal IOModules repository
  - L2 Switch with optional port security based on MAC and IP address
- CLI for debugging
  - Status of each IOModule on the hypervisor
  - Mapping of OVN info to IOModules

### IOVisor-OVN: next steps

- Extend IOModules repository with more network functions
  - Router
  - NAT
- Extend the architecture to handle multiple hypervisors
- Investigate possible optimization strategies when distributed network functions are needed

## How to try OVN-IOVisor

- Full stack deployable through DevStack
  - OpenStack, OVN\*, Hover, IOVisor-OVN and all the associated dependencies
    - OVN\*: vanilla OVN, with only OvS control plane (no data plane)
  - Single compute node
- More info:
  - https://github.com/netgroup-polito/iovisor-ovn/

#### Demo Overview

- Single node DevStack setup, with IOVisor-OVN as network backend
- Logical steps:

- Create an L2 Network
- Instantiate two VMs connected to that network
- VM1 and VM2 can ping each other
- Now, change (manually) the IP address on VM2
  - Security rule no longer appropriate
- Ping does no longer work
